world to see or, perhaps, the credentials for a mail server or database. For this reason, you are advised to use a generic page to report an error condition to the user.

12.1.2 ExceptionHandlerMiddleware

Use the `UseExceptionHandler` method within the application pipeline configuration to add `ExceptionHandlerMiddleware` to the application for capturing and displaying details of exceptions. The default template includes this middleware only if the application is not running in Development mode (listing 12.3). The middleware is positioned right at the start of the pipeline, so it can catch all exceptions. The method optionally takes a string representing the path to the page that should be displayed in the event of an unhandled exception occurring. When an exception happens, the middleware catches it, logs it, and reexecutes the request, so the configured error page can be displayed.

Listing 12.3 `ExceptionHandlerMiddleware`

```
if (!app.Environment.IsDevelopment())      ❶
{
    app.UseExceptionHandler("/Error");     ❷
}
```

❶ The condition checks whether the environment is Development.

❷ If it is not, you include the ExceptionHandlerMiddleware in the pipeline.

The default template configures the custom error page, named Error, which is included in the Pages folder. Given that this page is part of your application, it is easy to customize the content to your liking. If you prefer to use a different page to communicate an error condition to your users, change the value passed into the `UseExceptionHandler` method in Program.cs:
