Both methods take a format string that indicates where a page for the specific status code is to be found. The difference between them is in how they operate in the event that they are needed. The first method redirects the user to the specified error page, whereas the second reexecutes the request pipeline but changes the actual page being executed to the custom error page.

12.2.1 Exploring WithRedirects

When you use the `WithRedirects` version, the StatusCodePages middleware intercepts responses that have a status code in the 400-599 range, changes the status code to a 302 Temporarily Moved code, and includes the location of the custom error page within the location header of the response. The browser then makes another request, this time, for the error page, which is presented to the user. The status code for this request is 200 OK. This is illustrated in figure 12.5.
