they can see if there is anything obviously wrong with it. When doing so, you would usually render `Request.Path` or similar, but the StatusCodePages middleware changes the request to the custom error page, so `Request.Path` will resolve to /errors/404.

All is not lost, however, because the StatusCodePages middleware adds a feature called `IStatusCodeReExecuteFeature` to the `HttpContext`, where details of the original request are retained; you will be able to access that to get the original request URL. The example in the following listing shows how to access this feature to extract the original request path.

Listing 12.7 Accessing the original request path when the request is reexecuted

```
public class _404Model : PageModel
{
    public string RequestUrl { get; set; }                                    ❶

    public void OnGet()
    {
        var feature =
        ➥ HttpContext.Features.Get<IStatusCodeReExecuteFeature>();           ❷
        RequestUrl = feature?.OriginalPath;                                   ❸
    }
}
```

❶ Create a public property to store the request URL.

❷ Access the IStatusCodeReExecuteFeature, which the StatusCodePages middleware should have added to the HttpContext.

❸ Assign the OriginalPath property to the RequestUrl.

In addition to the `OriginalPath` property, you can obtain details of any query string values via the `OriginalQueryString` property or route values from the `RouteValues` property. Finally, amend the content of the custom 404 page as follows.
