Now that you have a basic understanding of logging within ASP.NET Core, you will look at how to configure logging within your application.

12.3.6 Applying log filter rules

I've discussed filtering logs according to their level, category, and so on. Now it's time to look at ways to specify *rules* you can apply to filtering logs. The recommended way to specify log-filtering rules is via the application's main configuration file—appSettings.json—within the `Logging` section. Take a look at the default template version of the relevant section (listing 12.12).

Listing 12.12 The `Logging` section in the appSettings.json file

```
"Logging": {
  "LogLevel": {                          ❶
    "Default": "Information",            ❷
    "Microsoft.AspNetCore": "Warning"    ❸
  }
}
```

❶ This is the log level property.

❷ The default minimum log level is Information.

❸ The minimum log level for the Microsoft.AspNetCore category is Warning.

The `LogLevel` property within the `Logging` section is where you define defaults for all logging providers. In this example, the minimum default log level is set to `Information`. That means only logs at `Information` level or above will be generated by all providers in all categories, unless a different rule is specified elsewhere. In the very next line, a different rule is indeed specified for all loggers in the `Microsoft.AspNetCore` category. This states that any logger that
