`EmailLoggerProvider` with the code shown in the following listing.

Listing 12.15 The `EmailLoggerProvider` class

```
using Microsoft.AspNetCore.Identity.UI.Services;

namespace CityBreaks.Logging
{
    public class EmailLoggerProvider : ILoggerProvider
    {
        private readonly IEmailSender _emailService;

        public EmailLoggerProvider(IEmailSender emailService)
        {
            _emailService = emailService;
        }

        public ILogger CreateLogger(string categoryName)
        {
            return new EmailLogger(emailService);
        }
        public void Dispose() { }
    }
}
```

The `ILoggerProvider` interface defines one method: `CreateLogger`. This method is responsible for instantiating an instance of the logger. Your logger takes a dependency on the `IEmailSender`, so you inject that and assign it to a field. The `ILoggerProvider` implements `IDisposable`, so you also need to include a `Dispose` method, although it does nothing in this example.

You register the `ILoggerProvider` with the service container:

```
builder.Services.AddTransient<ILoggerProvider, EmailLoggerProvider>();
```

Now it is ready to be used and will start writing any logs that have a log level of `Error` or `Critical`. To test this, you can manufacture an
