- With StatusCodePages middleware, you can incorporate the HTTP status code into the path or query string of the custom error page that is presented.
- Use the `WithRedirects` approach if you want StatusCodePages middleware to issue a redirect to the browser. The original status code and request path are replaced.
- Use the `WithReExecute` approach to retain the HTTP status code and the original path in the browser address bar.
- Logging is supported as a first-class citizen in Razor Pages applications.
- Default logging providers include `Console` and `Debug`.
- Log levels are used to denote log severity.
- Log categories help you identify the class that generated the log.
- Event IDs can be used to add metadata to logs.
- Recommended practice is to use named placeholders in format strings (templates) to generate log messages, so structured logging can extract their properties and values.
- Custom loggers consist of implementing the `ILogger` and `ILoggerProvider` interfaces, then registering the `ILoggerProvider` with the service container.
- Many third-party logging providers are available for ASP.NET Core applications.
- Structured logging generates logs in a structured format that facilitates advanced querying and filtering.
