❶ This is where the environment is set for this specific profile.

When you run the application, using Visual Studio or the `dotnet run` command, you can choose another profile with a different environment. Let's create a new one and try it out.

14.1.2 Setting the environment

In this section, you will control the environment the application runs within by creating a new launch profile for the application and setting the environment profile accordingly. After that, you will look at other ways to set the environment. To start, copy the existing CityBreaks profile, and paste the copy just before the existing final profile. Change the name of the profile to CityBreaksStaging, increment both port numbers by one, and set the `ASPNETCORE_ENVIRONMENT` to `Staging`.

Listing 14.2 Adding a new launch profile to the launchSettings.json file

```
"CityBreaksStaging": {                                                    ❶
  "commandName": "Project",
  "dotnetRunMessages": true,
  "launchBrowser": true,
  "applicationUrl": "https://localhost:7237;http://localhost:5237",       ❷
  "environmentVariables": {
    "ASPNETCORE_ENVIRONMENT": "Staging"                                   ❸
  }
},
```

❶ Name the profile CityBreaksStaging.

❷ Increment the port numbers by one.

❸ Set the environment to Staging.

If you are using Visual Studio, your new profile is added to the options in the launch dropdown shown in figure 14.1.
