### *14.1.3 Registering services conditionally for each environment*

In this section, you will create an alternative implementation of the Identity UI `IEmailSender` interface that will represent a production-ready version that should send email rather than create files to be stored on disk. In fact, your version won't generate or send email messages; it will simply log an informational message. Once you have created the implementation, you will use extension methods on the `WebApplicationBuilder` type to determine which version to register with the application's service container, based on the current runtime environment. You will start by adding a class to the Services folder named `ProductionEmailService`, using the code shown in the following listing.

**Listing 14.5 The `Production` version of `IEmailSender`**

```
using Microsoft.AspNetCore.Identity.UI.Services;

namespace CityBreaks.Services
{
    public class ProductionEmailService : IEmailSender                    ❶
    {
        private readonly ILogger<ProductionEmailService> _logger;         ❷
        public ProductionEmailService(ILogger<ProductionEmailService> logger)❷
        {                                                                 ❷
            _logger = logger;                                             ❷
        }                                                                 ❷

        public Task SendEmailAsync(string email,
        ➥ string subject, string htmlMessage)
        {
            _logger.LogInformation("Production email service used");      ❸
            return Task.CompletedTask;
        }
    }
}
```
