application configuration, including logging, across different environments.

14.1.5 The environment tag helper

The environment tag helper supports rendering different content dependent on the current environment. You might use this tag helper to load different versions of script and CSS files, depending on whether the application is running in production or development. For example, it is common to include the full local version of a JavaScript or CSS file when you are developing because it makes debugging easier. When the application is in production, you aim to minimize the number and size of HTTP requests, so you use a tool to *minify* and bundle your external resources, or you might rely on a CDN-hosted version if it is a popular library, such as Bootstrap or jQuery.

The environment tag helper has three attributes, two of which behave identically. They are described in table 14.1. The example in listing 14.8 shows how to use the environment tag helper to load the local version of Bootstrap during development and a CDN-hosted version for all other environments, using the `include` and `exclude` attributes. If an environment name is part of an exclude list, the content will not be rendered under any circumstances for that environment. Inclusion in the exclude list overrides inclusion in the include list or the names list.

Table 14.1 The environment tag helper attributes

Attribute	Description
`names`	The name(s) of the environment(s) for which the content should be rendered
`include`	The name(s) of the environment(s) for which the content should be rendered
`exclude`	The name(s) of the environment(s) for which the content should not be rendered
