You can add other stores, such as XML files, .ini files, and so on, if required. Configuration is added to the dependency injection system and is accessible throughout the application via the `IConfiguration` service.

14.2.1 appSettings.json

The vast majority of applications are likely to only ever use an appSettings.json file for their configuration needs. Each configuration setting is stored in its own section. As you learned in the previous chapter, the default appSettings.json file includes a section that configures logging for the application along with an `AllowedHosts` property.

Listing 14.9 Default appSettings.json file

```
{
  "Logging": {
    "LogLevel": {
      "Default": "Information",
      "Microsoft.AspNetCore": "Warning"
    }
  },
  "AllowedHosts": "*"
}
```

`Logging` and `AllowedHosts` are referred to as *well-known* configuration settings, along with `ConnectionStrings` (which you have used in your application to connect to the database) and `Kestrel` (for configuring the Kestrel web server); all of which enjoy IntelliSense support in Visual Studio and VS Code. In addition to these well-known settings, you can add your own custom settings to extend application configuration.

WORKING WITH CUSTOM SETTINGS
