will create a class to represent the SMTP settings and leverage the binding system that is included as part of configuration to hydrate an instance, using the appSettings .json as the source for the data.

14.2.3 Strongly typed app settings

The configuration system's built-in capability to bind settings to a C# object is extremely useful because it enables you to work with configuration settings in a strongly typed manner. For binding to work, your class must not be abstract, and it must have a default empty constructor. The following listing shows a C# representation of the `SmtpSettings` section from your appSettings.json file that meets these criteria.

Listing 14.12 The `SmtpSettings` and `Credentials` classes

```
public class SmtpSettings
{
    public string Host { get; init; }
    public int Port { get; init; }
    public bool StartTls { get; init; }
    public Credentials Credentials { get; init; }
}

public class Credentials
{
    public string UserName { get; init; }
    public string Password { get; init; }
}
```

You can use the `IConfiguration.Get<T>` method to attempt to bind a specific configuration section to the type specified by the `T` parameter. You create a field in the `ProductionEmailService` class to hold an instance of `SmtpSettings`, and then within the constructor, you bind the `SmtpSettings` section contents to it.
