Now that all the pieces are in place, you can replace the content in the home page with the view component using the view component tag helper, again shown in bold font in the following listing.

Listing 14.22 Using the view component tag helper

```
@page
@model IndexModel
@{
    ViewData["Title"] = "Home page";
}

<h1>City Breaks</h1>
<div class="container">
    <div class="row">
        <vc:cities />
    </div>
</div>
```

The final step is to comment out the `OnGetAsync` method in the existing \Pages\ Index.cshtml.cs file and then run the application. You should see no visible difference, except this time the content is being generated by the view component, not the page itself. This should be confirmed by the logging output. Each time you refresh the page, the message should be logged again.

Now that you have a view component, you can test the use of the cache tag helper. Modify the code around the view component tag helper, so it is the same as the following listing. You simply wrap the view component in a cache tag helper.

Listing 14.23 The cache tag helper

```
<h1>City Breaks</h1>
<div class="container">
    <div class="row">
        <cache>                ❶
            <vc:cities />
        </cache>               ❶
```
