VS Code users should make sure that their terminal is located in the project folder—the one containing the csproj file—and then execute the following command:

```
dotnet new page -n Welcome -o Pages -na WebApplication1.Pages
```

The `new page` command adds a Razor page to the application. The `-n` (or `--name`) option specifies the *name* the page should be created with. The `-o` (or `--output`) option specifies the *output location* where the page will be placed. And the `-na` (or `--namespace`) option specifies the *namespace* that should be applied to generated C# code files. Alternatively, you could navigate to the Pages folder to create the page and omit the `-o` option. If you do that, you will have to remember to navigate back into the folder containing the csproj file to perform the `run` command without additional arguments.

Visual Studio users don't need to specify a namespace. The default namespace applied to code files created with the Visual Studio wizard is automatically generated by concatenating the project name with their location within the project.

Now run the application. Remember, it's Ctrl-F5 in Visual Studio, while CLI users (VS Code or Visual Studio) should execute `dotnet watch run` in the terminal this time (not `dotnet run`) and then open a browser and navigate to the first URL that is logged to the terminal. Navigate to /welcome. The page should appear without any content apart from the header and footer (figure 2.7).
