`NotFoundResult`. The replacement code for the `OnGetAsync` method is shown in the following listing.

Listing 14.26 The `CityCheckMiddleware` class

```
public async Task<IActionResult> OnGetAsync()
{
    var cities = await _cityService.GetCityNamesAsync();              ❶
    if (cities.Contains(Name.ToLowerInvariant().Replace("-", " ")))   ❷
    {
        City = await _cityService.GetByNameAsync(Name);
        return Page();
    }
    else
    {
        return NotFound();                                             ❸
    }
}
```

❶ Get the list of city names from the CityService.

❷ Check the list of cities to see if it includes the one bound to the City property. If it exists, get the details from the database.

❸ Otherwise, set the status code to 404, Not Found.

Then run the application, and visit a City page. You should see an initial log message confirming the cache is empty and the cities are being stored there. Then revisit the home page and follow a link to any other City page. See from the logs that the cache is being used now, saving unnecessary database processing.

Finally, you are ready to present your application to the world. In the final section of this book, you will look at how to prepare your application for deployment in a process known as *publishing*.

14.4 Publishing your application
