You can edit the configuration by clicking the pencil icon next to each setting or by clicking the link to Show all settings, which gives you access to the settings. Take a look at the contents of the target runtime selector. As well as Portable, it includes a variety of operating system and architecture configurations. If you leave the selection as Portable, architecture-specific files are included for all platforms in a folder named Runtimes as part of the published output, increasing the size of the deployment. Ideally, you should select the target runtime if you know what it is. For example, if you are deploying your application to a server that runs IIS, you should select `win-x64`.

When you save your configuration, it is saved to a publish settings file—one with a .pubxml extension in a folder named PublishProfiles, which, in turn, is placed in the Properties folder. This is the kind of file the Import Profile option expects if you are to choose that option from the initial dialog. Given the content is XML, it is easy to modify in a text-based editor if you wish. You can create as many publish profiles as you want. Once you have created your profile, ensure it is selected and click the Publish button. Once the process has completed, you can click the link next to the Target Location setting to access the output location and see the published output.

THE PUBLISHED OUTPUT

Figure 14.2 shows the published output that results from publishing a web application that consists purely of the project template files. It has no third-party dependencies and gives you a clear picture of the published artifacts without any interference from the various dependencies your CityBreaks application has acquired along its journey.
