`build` and `publish` will be executed by the latest version of the .NET Core SDK installed on the machine. This can result in a published application referencing dependencies that don't exist on a hosting server.

To prevent accidentally building and publishing your application against a newer version of the .NET Core SDK than is supported by your host, you can fix the version your application targets. You do this by adding a global.json file to the directory structure of the project. This can be placed in either the folder containing the .csproj file or any of its parent folders.

The global.json file has an `sdk` node that is used to specify the version of the .NET Core SDK to use when executing commands against the project (including publishing). The example in the following listing fixes the version at 6.0.101.

Listing 14.28 Fixing the SDK version in global.json

```
{
  "sdk": {
    "version": "6.0.101"
  }
}
```

You can use the dotnet CLI to generate a global.json file. Navigate to the folder in which you want to create the file, and run the following command, which specifies the `sdk` version via the `sdk-version` option:

```
dotnet new globaljson --sdk-version 6.0.101
```

Summary

- Environments enable you to adjust the configuration of your application based on where it is running.
