- The environment setting is taken from an environment variable, and if none exists, it defaults to `Production`.
- Launch profiles configure your application to run in `Development`.
- You can use the environment tag helper to manage different environment-based configurations within your pages.
- The primary source of application configuration information is the appSettings .json file.
- You can use a string-based indexer to access configuration information via the `IConfiguration` service.
- You can also bind configuration sections to your own objects in a strongly typed manner.
- Alternatively, you can use the options pattern to bind configuration sections to business objects.
- App settings files can be customized to a particular environment by including the environment name within the filename.
- Caching can improve performance by reducing the number of calls to external processes, such as databases.
- Default caching is saved to memory and is cleared when the application restarts.
- The cache tag helper can be used to store generated sections of HTML.
- The `IMemoryCache` service can be injected into classes that need it.
- You can set absolute or sliding expiry on cached items.
- Publishing is the process that prepares an application for deployment.
