template are Bootstrap, a popular CSS framework; jQuery, a cross-browser JavaScript utility library; and two validation libraries based on jQuery. They are used for validating form submissions.

The folder structure within wwwroot is not set in stone. You can move things around as you like.

2.2.6 The Pages folder

By convention, the Pages folder is configured as the home of your Razor page files. It is where the framework expects to find your Razor pages.

The project template starts you off with three pages. You have already seen two of them—Index, or the home page, and the Privacy page. And of course, your example includes the Welcome page you created. The third page provided by the project template is Error. Looking at the actual folder on disk, you will notice that each page comprises two files—one with a .cshtml extension (a Razor file) and another that ends with .cshtml.cs (a C# code file). This might not be immediately obvious when you look at Solution Explorer. The files are nested by default (figure 2.10). You can see them by disabling file nesting in the toolbar at the top of Solution Explorer or by clicking the expander icon next to the page, which will reveal not just the nested file but a tree showing an outline of the C# class, including properties, fields, and methods.
