the specified time, the server should return a 304 Not Modified status code; otherwise, it should send the modified resource. Other headers might inform the server of the preferred language for the response or the types of content the requester can handle.

The request can also include cookies—snippets of information stored by the browser that may or may not be specific to the website's user. The most common uses for cookies include the storage of the user's authentication status, once they have logged in to a site, or a token, which uniquely identifies a visitor for analytics tracking purposes.

The request can also include a body. Typically, this applies to POST requests, where the body contains the form values being submitted to the server.

The response returned by the server is structured in a similar way. It features a status line, which specifies the protocol version being used, the HTTP status code, and some text to describe the result—officially known as a *reason phrase*. An example status line might look like this:

```
HTTP/1.1 200 OK
```

The response can also include headers, which might specify the content type of the data being sent, its size, and the method used to encode the response if it has been encoded, such as gzip. The response usually includes a body containing the data that has been requested.

2.3.2 The HttpContext

All of the information in an HTTP transaction needs to be made available to your Razor Pages application. The object used to encapsulate details of the current HTTP transaction—the request and the response—is the
