Property	Description
`ContentLength`	The size of the response in bytes, which is assigned to the content-length header.
`ContentType`	The media type of the response, which is assigned to the content-type header.
`Cookies`	The cookie collection of the outgoing response.
`HasStarted`	Indicates whether the response headers have been sent to the client. If they have, you should not attempt to alter the response. If you do, the values provided in the content-length and content-type headers may no longer be valid, leading to unpredictable results at the client.
`Headers`	Provides access to the response headers.
`StatusCode`	The HTTP status code for the response (e.g., 200, 302, 404, etc.).
`WriteAsync`	An extension method that writes text to the response body, using UTF-8 encoding.
`Redirect`	Returns a temporary (302) or permanent (301) redirect response to the client, together with the location to redirect to.

The methods and properties detailed in the previous tables are useful when you are working directly with the request and response, which you will do when creating your own middleware, for example.

2.3.3 The application request pipeline

When the web server routes a request to your application, the application must decide how to handle it. A number of considerations need to be taken into account. Where should the request be directed or routed to? Should details of the request be logged? Should the application simply return the content of a file? Should it compress the response? What should happen if an exception is encountered while the request is being processed? Is the person making the request actually allowed to access the resource they have requested? How should cookies or other request-related data be handled?
