5. Run the application to see the default app, as shown in figure 23.5.

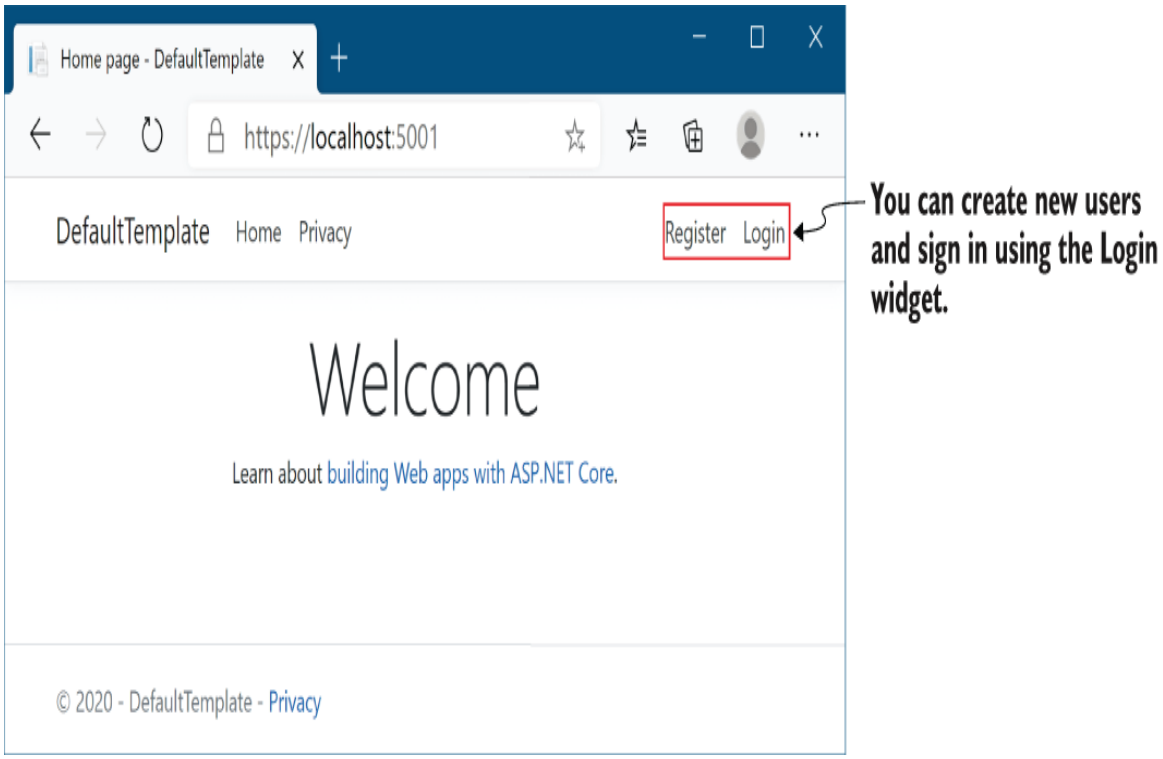

Figure 23.5 The default template with individual account authentication looks similar to the no authentication template, with the addition of a Login widget at the top right of the page.

NOTE The Visual Studio template configures the application to use LocalDB and includes EF Core migrations for SQL Server. If you want to use a different database provider, you can replace the configuration and migrations with your database of choice, as described in chapter 12.

This template should look familiar, with one twist: you now have Register and Login buttons! Feel free to play with the template—creating a user, logging in and out—to get a feel for the app. Once you're happy, look at the code generated by the template and the boilerplate it saved you from writing.

TIP Don't forget to run the included EF Core migrations before trying to create users. Run `dotnet ef database update` from the project folder.
