Visual Studio builds your application and then generates the Register.cshtml page for you, placing it in the Areas/Identity/Pages/Account folder. It also generates several supporting files, as shown in figure 23.13. These are required mostly to ensure that your new Register.cshtml page can reference the remaining pages in the default Identity UI.

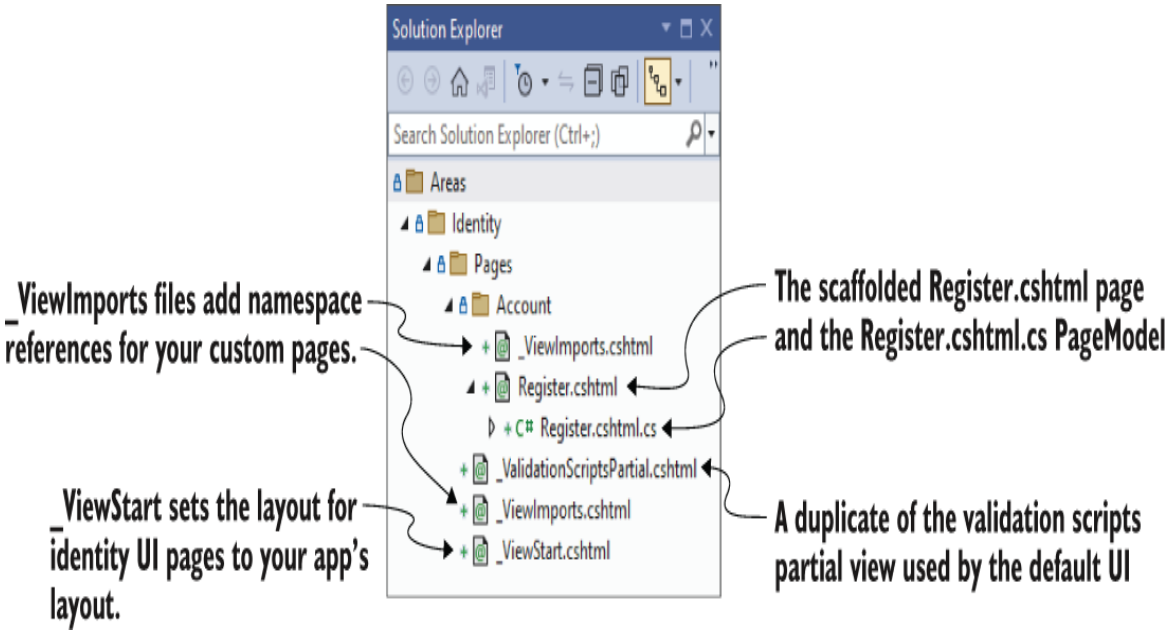

Figure 23.13 The scaffolder generates the Register.cshtml Razor Page, along with supporting files required to integrate with the remainder of the default Identity UI.

We're interested in the Register.cshtml page, as we want to customize the UI on the Register page, but if we look inside the code-behind page, Register.cshtml.cs, we see how much complexity the default Identity UI is hiding from us. It's not insurmountable (we'll customize the page handler in section 23.6), but it's always good to avoid writing code if we can help it.

Now that you have the Razor template in your application, you can customize it to your heart's content. The downside is that you're now maintaining more code than you were with the default UI. You didn't have to write it, but you may still have to update it when a new version of ASP.NET Core is released.
