authorization system and how you can use it to customize your apps; in particular, the recipe application, which is coming along nicely!

Summary

- Authentication is the process of determining who you are, and authorization is the process of determining what you're allowed to do. You need to authenticate users before you can apply authorization.
- Every request in ASP.NET Core is associated with a user, also known as a principal. By default, without authentication, this is an anonymous user. You can use the claims principal to behave differently depending on who made a request.
- The current principal for a request is exposed on `HttpContext.User`. You can access this value from your Razor Pages and views to find out properties of the user such as their, ID, name, or email.
- Every user has a collection of claims. These claims are single pieces of information about the user. Claims could be properties of the physical user, such as `Name` and `Email`, or they could be related to things the user has, such as `HasAdminAccess` or `IsVipCustomer`.
- Legacy versions of ASP.NET used roles instead of claims. You can still use roles if you need to, but you should typically use claims where possible.
