you're a regular flyer, and you've notched up enough miles to achieve Gold frequent-flyer status, so you can use the airline lounge.

You head to the lounge, where you're asked to present your Gold frequent-flyer card to the attendant, and they let you in. This is another example of authorization. You must have a `FrequentFlyerClass` claim with a value of `Gold` to proceed.

NOTE You've used authorization twice so far in this scenario. Each time, you presented a claim to proceed. In the first case, the presence of any `BoardingPassNumber` was sufficient, whereas for the `FrequentFlyerClass` claim, you needed the specific value of `Gold`.

When you're boarding the airplane, you have one final authorization step, in which you must present the `BoardingPassNumber` claim again. You presented this claim earlier, but boarding the aircraft is a distinct action from entering security, so you have to present it again.

This whole scenario has lots of parallels with requests to a web app:

- Both processes start with authentication.
- You must prove who you are to retrieve the claims you need for authorization.
- You use authorization to protect sensitive actions like entering security and the airline lounge.

I'll reuse this airport scenario throughout the chapter to build a simple web application that simulates the steps you take in an airport. We've covered the concept of authorization in general, so in the next section we'll look at how authorization works in ASP.NET Core. We'll start with the most basic level
