of authorization, ensuring that only authenticated users can execute an action, and look at what happens when you try to execute such an action.

24.2 Authorization in ASP.NET Core

In this section you'll see how the authorization principles described in the previous section apply to an ASP.NET Core application. You'll learn about the role of the `[Authorize]` attribute and `AuthorizationMiddleware` in authorizing requests to Razor Pages and MVC actions. Finally, you'll learn about the process of preventing unauthenticated users from executing endpoints and what happens when users are unauthorized.

The ASP.NET Core framework has authorization built in, so you can use it anywhere in your app, but it's most common to apply authorization via the `AuthorizationMiddleware`. The `AuthorizationMiddleware` should be placed after both the routing middleware and the authentication middleware but before the endpoint middleware, as shown in figure 24.2.
