The final task is adding `IsRecipeOwnerHandler` to the DI container. Your handler uses an additional dependency, `UserManager<>`, that uses EF Core, so you should register the handler as a scoped service:

```
services.AddScoped<IAuthorizationHandler, IsRecipeOwnerHandler>();
```

TIP If you're wondering how to know whether you register a handler as scoped or a singleton, think back to chapter 9. Essentially, if you have scoped dependencies, you must register the handler as scoped; otherwise, singleton is fine.

With everything hooked up, you can take the application for a spin. If you try to edit a recipe you didn't create by clicking the Edit button on the recipe, you'll either be redirected to the login page (if you hadn't yet authenticated) or see an "access denied" page, as shown in figure 24.7.
