- Authentication is the process of determining who a user is. It’s distinct from authorization, the process of determining what a user can do. Authentication typically occurs before authorization.
- You can use the authorization services in any part of your application, but it’s typically applied using the `AuthorizationMiddleware` by calling `UseAuthorization()`. This should be placed after the calls to `UseRouting()` and `UseAuthentication()`, and before the call to `UseEndpoints()` for correct operation.
- You can protect Razor Pages and MVC actions by applying the `[Authorize]` attribute. The routing middleware records the presence of the attribute as metadata with the selected endpoint. The authorization middleware uses this metadata to determine how to authorize the request.
- The simplest form of authorization requires that a user be authenticated before executing an action. You can achieve this by applying the `[Authorize]` attribute to a Razor Page, action, controller, or globally. You can also apply attributes conventionally to a subset of Razor Pages.
- Claims-based authorization uses the current user’s claims to determine whether they’re authorized to execute an action. You define the claims needed to execute an action in a policy.
