In section 27.1 you learned about the need to publish an app before you deploy it and the benefits of using a reverse proxy when you run an ASP.NET Core app in production. If you're deploying your application to Windows, IIS will likely be your reverse proxy and will be responsible for managing your application.

IIS is an old and complex beast, and I can't possibly cover everything related to configuring it in this book. Neither would you want me to; that discussion would be tedious! Instead, in this section I'll provide an overview of the basic requirements for running ASP.NET Core behind IIS, along with the changes you may need to make to your application to support IIS.

If you're on Windows and want to try these steps locally, you'll need to enable IIS manually on your development machine. If you've done this with older versions of Windows, nothing much has changed. You can find a step-by-step guide to configuring IIS and troubleshooting tips in the ASP.NET Core documentation at http://mng.bz/6g2R.

27.2.1 Configuring IIS for ASP.NET Core

The first step in preparing IIS to host ASP.NET Core applications is installing the ASP.NET Core Windows Hosting Bundle (http://mng.bz/opED). This includes several components needed to run .NET apps:

- *The .NET Runtime*—Runs your .NET 7 application
- *The ASP.NET Core Runtime*—Required to run ASP.NET Core apps
- *The IIS AspNetCore Module*—Provides the link between IIS and your app so that IIS can act as a reverse proxy
