endpoint. The request continues down the middleware pipeline until it reaches the endpoint middleware, which executes the lambda and returns the `string` value in the response body.

The other endpoint defines a lambda to run for `GET` requests to the `/person` path, but it returns a C# record instead of a `string`. When you return a C# object from a minimal API endpoint, the object is serialized to JSON automatically and returned in the response body, as you saw in figure 3.8. In chapter 6 you'll learn how to customize this response, as well as return other types of responses.

And there you have it. You've finished the tour of your first ASP.NET Core application! Before we move on, let's take one last look at how our application handles a request. Figure 3.9 shows a request to the `/person` path being handled by the sample application. You've seen everything here already, so the process of handling a request should be familiar. The figure shows how the request passes through the middleware pipeline before being handled by the endpoint middleware. The endpoint executes the lambda method and generates the JSON response, which passes back through the middleware to the ASP.NET Core web server before being sent to the user's browser.
