- http://localhost:5001—This address is accessible only on your local computer, so it will not accept requests from the wider internet.
- http://*:5002—Any URL on port 5002. External requests from the internet can access the app on port 5002, using any URL that maps to your computer.

Note that you can't specify a different hostname, like tastyrecipes.com. ASP.NET Core listens to all requests on a given port; it doesn't listen for specific domain names. The exception is the localhost hostname, which allows only requests that came from your own computer.

NOTE If you find the `ASPNETCORE_URLS` variable isn't working properly, ensure that you don't have a launchSettings.json file in the directory. When present, the values in this file take precedence. By default, launchSettings.json isn't included in the `publish` output, so this generally won't be a problem in production.

Setting the URL of an app using a single environment variable works great for some scenarios, most notably when you're running a single application in a virtual machine, or within a Docker container.

TIP ASP.NET Core is well suited to running in containers but working with containers is a separate book in its own right. For details on hosting and publishing apps using Docker, see Microsoft's "Host ASP.NET Core in Docker containers" documentation: http://mng.bz/e5GV.

If you're not using Docker containers or a PaaS offering, chances are that you're hosting multiple apps side-by-side on the same machine. A single environment variable is no good for setting URLs in this case, as it would change the URL of every app.
