- If you are using a custom web application builder with IIS, ensure that you call `UseIISIntegration()` and `UseIIS()` so that IIS forwards the request to your app correctly. If you're using the default `WebApplicationBuilder`, these methods are called automatically for you.
- When you publish your application using the .NET CLI, a web.config file is added to the output folder. It's important that this file be deployed with your application when publishing to IIS, as it defines how your application should run.
- The URL that your app listens on is specified by default using the environment variable `ASPNETCORE_URLS`. Setting this value changes the URL for all the apps on your machine. Alternatively, pass the `--urls` command-line argument when running your app, as in this example: `dotnet app.dll --urls http://localhost:80`.

---

[1] I ran into this problem myself. You can read about it in detail and how I solved it on my blog: http://mng.bz/aoem.
