

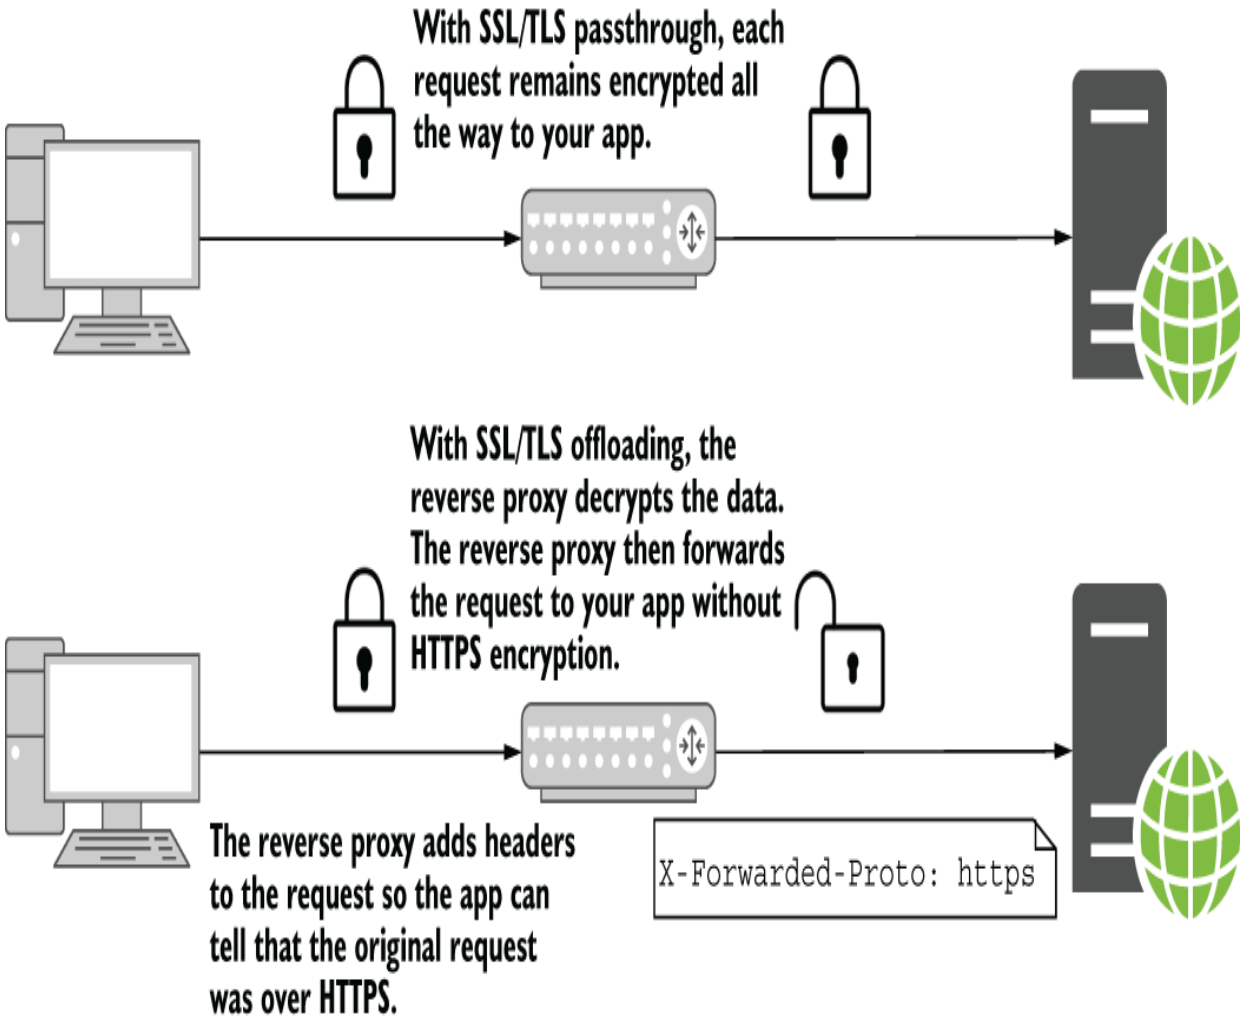

Figure 28.3 You have two options when using HTTPS with a reverse proxy: SSL/TLS passthrough and SSL/TLS offloading. In SSL/TLS passthrough, the data is encrypted all the way to your ASP.NET Core app. For SSL/TLS offloading, the reverse proxy handles decrypting the data, so your app doesn't have to.

With SSL/TLS offloading, instead of your application handling requests using HTTPS directly, your app continues to use HTTP. The reverse proxy is responsible for encrypting and decrypting HTTPS traffic to the browser. This often gives you the best of both worlds: data is encrypted between the
