TIP If you've tried trusting the certificate, and your app is still giving errors, try closing all your browser windows and running `dotnet dev-certs https --clean` followed by `dotnet dev-certs https --trust`. Browsers cache certificate trust, so the close and open step is important!

The ASP.NET Core and IIS development certificates make it easy to use Kestrel with HTTPS locally, but those certificates won't help once you move to production. In the next section I show how to configure Kestrel to use a production TLS certificate.

28.3 Configuring Kestrel with a production HTTPS certificate

Creating a TLS certificate for production is often a laborious process, as it requires proving to a third-party CA that you own the domain you're creating the certificate for. This is an important step in the trust process and ensures that attackers can't impersonate your servers. The result of the process is one or more files, which is the HTTPS certificate you need to configure for your app.

TIP The specifics of how to obtain a certificate vary by provider and by your OS platform, so follow your provider's documentation carefully. The vagaries and complexities of this process are one of the reasons I strongly favor the SSL/TLS-offloading or "one-click" approaches described previously. Those approaches mean my apps don't need to deal with certificates, and I don't need to use the approaches described in this section; I delegate that responsibility to another piece of the network, or to the underlying platform.
