

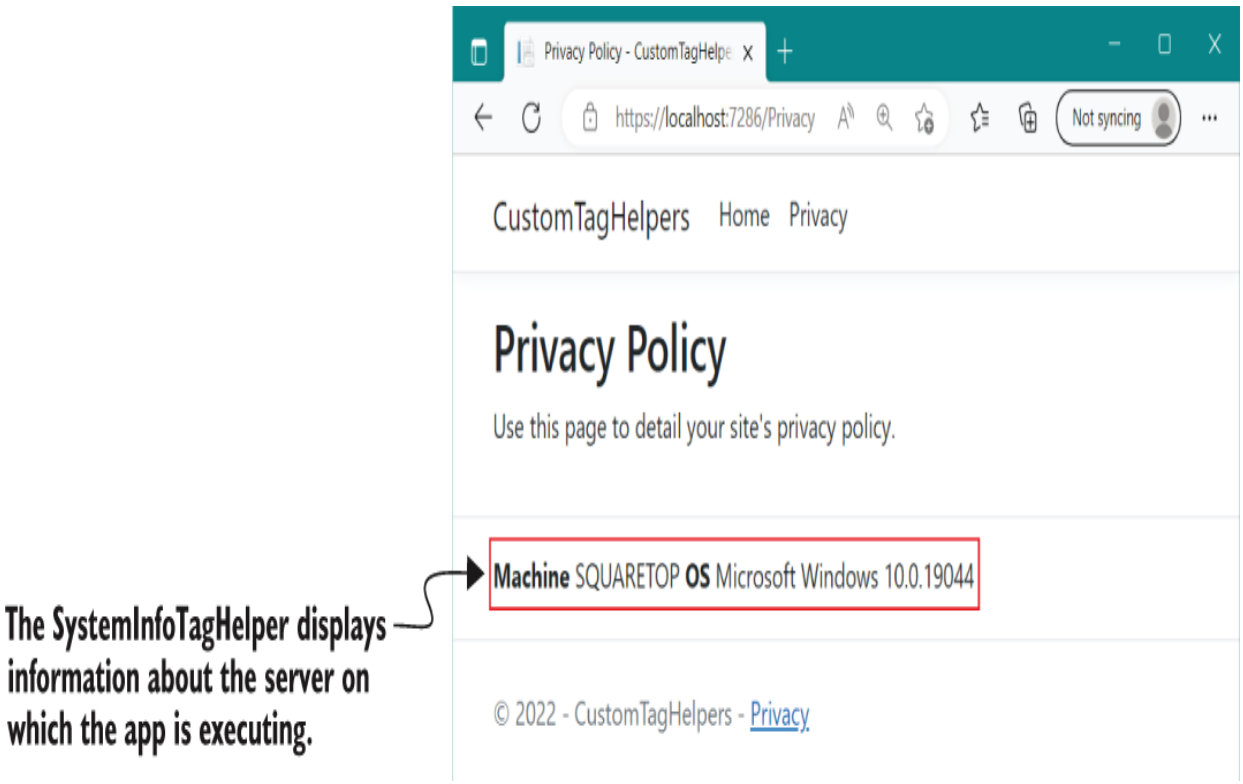

Figure 32.1 The `SystemInfoTagHelper` displays the machine name and operating system on which the application is running. It can be useful for identifying which instance of your app handled the request when running in a web-farm scenario.

You can call this Tag Helper from Razor by creating a `<system-info>` element in your template:

```
<footer>
  <system-info></system-info>
</footer>
```

TIP You might not want to expose this sort of information in production, so you could also wrap it in an `<environment>` Tag Helper, as you saw in chapter 18.
