- *Collection rules*—When types contain collections, such as `List<T>`, you can apply validation to each item in the list, as well as to the overall collection.
- *RuleSets*—You can create multiple collections of rules that can be applied to an object in different circumstances. These can be especially useful if you're using FluentValidation in additional areas of your application.
- *Client-side validation*—FluentValidation is a server-side framework, but it emits the same attributes as `DataAnnotations` attributes to enable client-side validation using jQuery.

There are many more features, so be sure to browse the documentation at https://docs.fluentvalidation.net for details. In the next section you'll see how to add FluentValidation to your ASP.NET Core application.

32.4.2 Adding FluentValidation to your application

Replacing the whole validation system of ASP.NET Core sounds like a big step, but the FluentValidation library makes it easy to add to your application. Simply follow these steps:

1. Install the FluentValidation.AspNetCore NuGet package using Visual Studio's NuGet package manager via the command-line interface (CLI) by running `dotnet add package FluentValidation.AspNetCore` or by adding a `<PackageReference>` to your .csproj file:

```
<PackageReference Include="FluentValidation.AspNetCore" Version="11.2.2" />
```
