4.2.2 Simple pipeline scenario 2: Handling static files

In this section, I'll show you how to create one of the simplest middleware pipelines you can use for a full application: a static-file application. Most web applications, including those with dynamic content, serve some pages by using static files. Images, JavaScript, and CSS stylesheets are normally saved to disk during development and are served up when requested from the special wwwroot folder of your project, normally as part of a full HTML page request.

DEFINITION By default, the wwwroot folder is the only folder in your application that ASP.NET Core will serve files from. It doesn't serve files from other folders for security reasons. The wwwroot folder in an ASP.NET Core project is typically deployed as is to production, including all the files and folders it contains.

You can use `StaticFileMiddleware` to serve static files from the wwwroot folder when requested, as shown in figure 4.7. In this example, an image called moon.jpg exists in the wwwroot folder. When you request the file using the `/moon.jpg` path, it's loaded and returned as the response to the request.
