That’s my preference. Of course, you’re free to adopt another approach if you prefer.

That brings us to the end of this chapter on custom Razor Pages components. When you combine it with the components in the previous chapter, you’ve got a great base for extending your ASP.NET Core applications to meet your needs. It’s a testament to ASP.NET Core’s design that you can swap out whole sections like the Validation framework entirely. If you don’t like how some part of the framework works, see whether someone has written an alternative!

Summary

- With Tag Helpers, you can bind your data model to HTML elements, making it easier to generate dynamic HTML. Tag Helpers can customize the elements they’re attached to, add attributes, and customize how they’re rendered to HTML. This can greatly reduce the amount of markup you need to write.
- The name of a Tag Helper class dictates the name of the element in the Razor templates, so the `SystemInfoTagHelper` corresponds to the `<system-info>` element. You can choose a different element name by adding the `[HtmlTargetElement]` attribute to your Tag Helper.
- You can set properties on your Tag Helper object from Razor syntax by decorating the property with an `[HtmlAttributeName("name")]` attribute and providing a name. You can set these properties from Razor using HTML attributes, as in `<system-info name="value">`.
