- The `TagHelperOutput` parameter passed to the `Process` or `ProcessAsync` methods control the HTML that's rendered to the page. You can set the element type with the `TagName` property and set the inner content using `Content.SetContent()` or `Content.SetHtmlContent()`.
- You can prevent inner Tag Helper content from being processed by calling `SupressOutput()`, and you can remove the element by setting `TagName=null`. This is useful if you want to conditionally render elements to the response.
- You can retrieve the contents of a Tag Helper by calling `GetChildContentAsync()` on the `TagHelperOutput` parameter. You can then render this content to a `string` by calling `GetContent()`. This will render any Razor expressions and Tag Helpers to HTML, allowing you to manipulate the contents.
- View components are like partial views, but they allow you to use complex business and rendering logic. You can use them for sections of a page, such as the shopping cart, a dynamic navigation menu, or suggested articles.
- Create a view component by deriving from the `ViewComponent` base class and implementing `InvokeAsync()`. You can pass parameters to this function from the Razor view template using HTML attributes, in a similar way to Tag Helpers.
