Figure 33.6 You can use a custom `HttpMessageHandler` to modify requests before they're sent to third-party APIs. Every request passes through the custom handler before the final handler (the `HttpClientHandler`) sends the request to the HTTP API. After the response is received, each handler gets a chance to inspect and modify the response.

To create a custom `HttpMessageHandler` and add it to a typed or named client's pipeline, follow these steps:

1. Create a custom handler by deriving from the `DelegatingHandler` base class.
2. Override the `SendAsync()` method to provide your custom behavior. Call `base.SendAsync()` to execute the remainder of the handler pipeline.
3. Register your handler with the DI container. If your handler does not require state, you can register it as a singleton service; otherwise, you should register it as a transient service.
4. Add the handler to one or more of your named or typed clients by calling `AddHttpMessageHandler<T>()` on an `IHttpClientBuilder`, where `T` is your handler type.
   The order in which you register handlers dictates the order in which they are added to the `HttpClient` handler pipeline.
   You can add the same handler type more than once in a pipeline if you wish and to multiple typed or named clients.

The following listing shows an example of a custom `HttpMessageHandler` that adds a header to every outgoing request. We use the custom `"API-KEY"` header in this example, but the header
