```
app.MapGet("/", async (ExchangeRatesClient ratesClient) =>    ❶
    await ratesClient.GetLatestRatesAsync());                 ❷
```

❶ A typed client created using IHttpClientFactory is injected using dependency injection (DI).

❷ The typed client is used to retrieve exchange rates from the remote API and returns them.

A simple optimization for this code might be to cache the exchange rate values for a period. There are multiple ways you could implement that, but in this section we'll use a simple cache that preemptively fetches the exchange rates in the background, as shown in figure 34.1. The API endpoint simply reads from the cache; it never has to make HTTP calls itself, so it remains fast.
