look at two supported ways of running your application: as a Windows Service or as a Linux systemd daemon.

34.2.2 Running worker services in production

In this section you'll learn how to run worker services in production. You'll learn how to install a worker service as a Windows Service so that the operating system monitors and starts your worker service automatically. You'll also see how to prepare your application for installation as a systemd daemon in Linux.

Worker services, like ASP.NET Core applications, are fundamentally .NET console applications. The difference is that they are typically intended to be long-running applications. The common approach for running these types of applications on Windows is to use a Windows Service or to use a systemd daemon in Linux.

NOTE It's also common to run applications in the cloud using Docker containers or dedicated platform services like Azure App Service. The process for deploying a worker service to these managed services is typically identical to deploying an ASP.NET Core application.

Adding support for Windows Services or systemd is easy, thanks to two optional NuGet packages:

- *Microsoft.Extensions.Hosting.Systemd*—Adds support for running the application as a systemd application. To enable systemd integration, call `UseSystemd()` on your `IHostBuilder` in Program.cs.
