clustering so that you can run multiple instances of your application and distribute the jobs among them.

34.3.1 Installing Quartz.NET in an ASP.NET Core application

In this section I show how to install the Quartz.NET scheduler into an ASP.NET Core application. Quartz.NET runs in the background in the same way as the `IHostedService` implementations do. In fact, Quartz.NET uses the `IHostedService` abstractions to schedule and run jobs.

DEFINITION A *job* in Quartz.NET is a task to be executed that implements the `IJob` interface. It is where you define the logic that your tasks execute.

Quartz.NET can be installed in any .NET 7 application, so in this chapter I show how to install Quartz.NET in a worker service using the generic host rather than an ASP.NET Core app using minimal hosting. You'll install the necessary dependencies and configure the Quartz.NET scheduler to run as a background service. In section 34.3.2 we'll convert the exchange-rate downloader task from section 34.1 to a Quartz.NET `IJob` and configure triggers to run on a schedule.

NOTE The instructions in this section can be used to install Quartz.NET in either a worker service or a full ASP.NET Core application. The only difference is whether you use the generic host in Program.cs or `WebApplicationBuilder`.

To install Quartz.NET, follow these steps:
