- Middleware has a similar role to HTTP modules and handlers in ASP.NET but is easier to reason about.
- Middleware is composed in a pipeline, with the output of one middleware passing to the input of the next.
- The middleware pipeline is two-way: requests pass through each middleware on the way in, and responses pass back through in reverse order on the way out.
- Middleware can short-circuit the pipeline by handling a request and returning a response, or it can pass the request on to the next middleware in the pipeline.
- Middleware can modify a request by adding data to or changing the `HttpContext` object.
- If an earlier middleware short-circuits the pipeline, not all middleware will execute for all requests.
- If a request isn't handled, the middleware pipeline returns a 404 status code.
- The order in which middleware is added to `WebApplication` defines the order in which middleware will execute in the pipeline.
- The middleware pipeline can be reexecuted as long as a response's headers haven't been sent.
- When it's added to a middleware pipeline, `StaticFileMiddleware` serves any requested files found in the wwwroot folder of your application.
- `DeveloperExceptionPageMiddleware` provides a lot of information about errors during development, but it should never be used in production.
