```
    new("Morgan", "Freeman"),                                    ❶
};                                                               ❶

app.MapGet("/person/{name}", (string name) =>                    ❷
    people.Where(p => p.FirstName.StartsWith(name)));            ❸

app.Run();
```

❶ Creates a list of people as the data for the API

❷ The route is parameterized to extract the name from the URL.

❸ The extracted value can be injected into the lambda handler.

If you send a request to `/person/Al` for the app defined in listing 5.1, the `name` parameter will have the value `"Al"`, and the API will return the following JSON:

```
[{"firstName":"Al","lastName":"Pacino"}]
```

NOTE By default, minimal APIs serialize C# objects to JSON. You'll see how to return other types of results in section 5.3.

The ASP.NET Core routing system is quite powerful, and we'll explore it in more detail in chapter 6. But with this simple capability, you can already build more complex applications.

5.2.2 Mapping verbs to endpoints

So far in this book we've defined all our minimal API endpoints by using the `MapGet()` function. This function matches requests that use the `GET` HTTP verb. `GET` is the most-used verb; it's what a browser uses when you enter a URL in the address bar of your browser or follow a link on a web page.
