

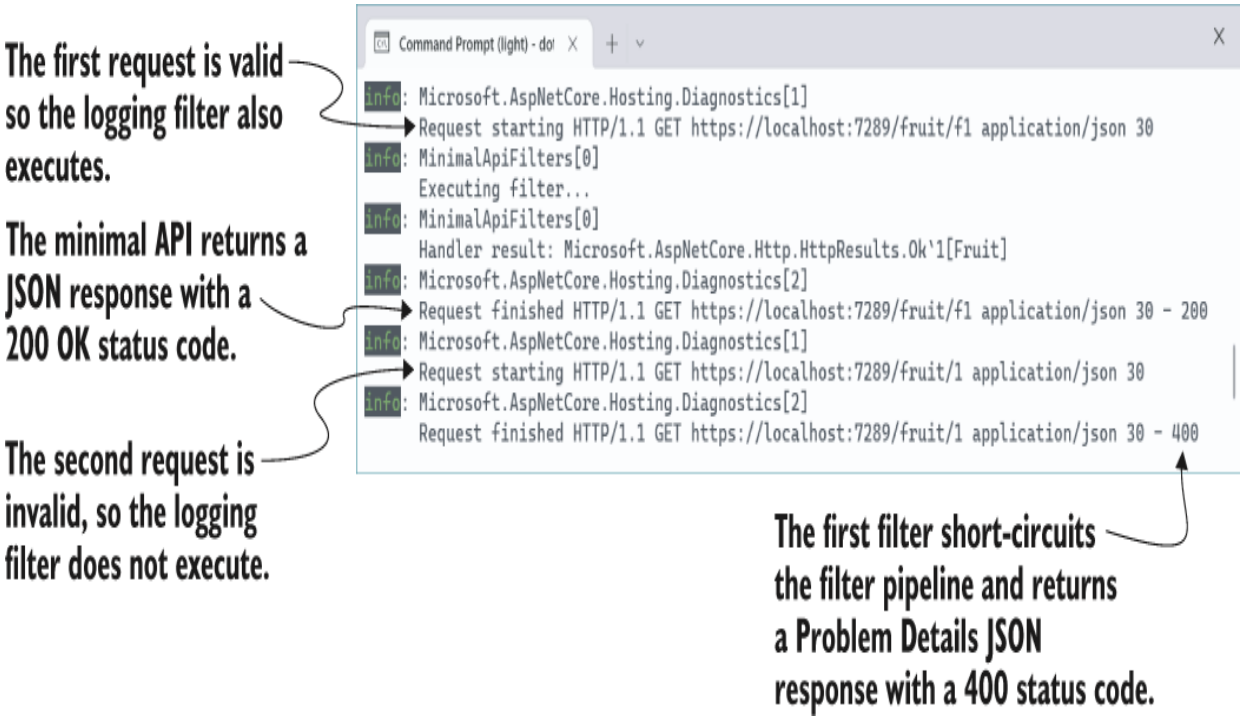

Figure 5.9 Sending two requests to the API from listing 5.10. The first request is valid, so both filters execute. An invalid `id` is provided in the second request, so the first filter short-circuits the requests, and the second filter doesn't execute.

By adding calls to `AddEndpointFilter`, you can create arbitrarily large endpoint filter pipelines, but the fact that you can doesn't mean you should. Moving code to filters can reduce clutter in your endpoints, but it makes the flow of your application harder to understand. I suggest that you avoid using filters unless you find duplicated code in multiple endpoints, and then favor a filter over a simple method call only if it significantly simplifies the code required.

5.4.2 Filters or middleware: Which should you choose?
