- Each HTTP response includes a status code. Common codes include `200 OK`, `201 Created`, `400 Bad Request`, and `404 Not Found`. It's important to use the correct status code, as clients use these status codes to infer the behavior of your API.
- An HTTP API exposes methods or endpoints that you can use to access or change data on a server using the HTTP protocol. An HTTP API is typically called by mobile or client-side web applications.
- You define minimal API endpoints by calling `Map*` functions on the `WebApplication` instance, passing in a route pattern to match and a handler function. The handler functions runs in response to matching requests.
- There are different extension methods for each HTTP verb. `MapGet` handles `GET` requests, for example, and `MapPost` maps `POST` requests. You use these extension methods to define how your app handles a given route and HTTP verb.
- You can define your endpoint handlers as lambda expressions, `Func<T, TResult>` and `Action<T>` variables, local functions, instance methods, or static methods. The best approach depends on how complex your handler is, as well as personal preference.
- Returning `void` from your endpoint handler generates a `200` response with no body by default. Returning a string generates a `text/plain` response. Returning an `IResult` instance can generate any response. Any other object returned from your endpoint handler is serialized to JSON. This convention helps keep your endpoint handlers succinct.
