Also, some methods available on `LinkGenerator` take an `HttpContext`. These methods are often easier to use in an endpoint handler, as they extract ambient values such as the scheme and hostname from the incoming request and reuse them for URL generation.

WARNING Be careful when using the `GetUriByName` method. It's possible to expose vulnerabilities in your app if you use unvalidated host values. For more information on host filtering and why it's important, see this post: http://mng.bz/V1d5.

In listing 6.2, as well as providing the route name, I passed in an anonymous object to `GetPathByName`:

```
string link = links.GetPathByName("product", new { name = "big-widget"});
```

This object provides additional route values when generating the URL, in this case setting the `name` parameter to `"big-widget"`.

If a selected route explicitly includes the defined route value in its definition, such as in the `"/product/{name}"` route template, the route value will be used in the URL path, resulting in `/product/big-widget`. If a route doesn't contain the route value explicitly, as in the `"/product"` template, the route value is appended to the query string as additional data. as in `/product?name=big-widget`.

6.4.2 Generating URLs with IResults

Generating URLs that link to other endpoints is common when you're creating a REST API, for example. But you don't always need to display URLs. Sometimes, you want to redirect a user to a URL automatically. In
