For every parameter in your minimal API endpoint handler, ASP.NET core must decide how to create the corresponding arguments. Minimal APIs can use six different binding sources to create the handler arguments:

- *Route values*—These values are obtained from URL segments or through default values after matching a route, as you saw in chapter 5.
- *Query string values*—These values are passed at the end of the URL, not used during routing.
- *Header values*—Header values are provided in the HTTP request.
- *Body JSON*—A single parameter may be bound to the JSON body of a request.
- *Dependency injected services*—Services available through dependency injection can be used as endpoint handler arguments. We look at dependency injection in chapters 8 and 9.
- *Custom binding*—ASP.NET Core exposes methods for you to customize how a type is bound by providing access to the `HttpRequest` object.

WARNING Unlike MVC controllers and Razor Pages, minimal APIs do *not* automatically bind to the body of requests sent as forms, using the `application/ x-www-form-urlencoded` mime type. Minimal APIs will bind only to a JSON request body. If you need to work with form data in a minimal API endpoint, you can access it on `HttpRequest.Form`, but you won't benefit from automatic binding.

We'll look at the exact algorithm ASP.NET Core uses to choose which binding source to use in section 7.8, but we'll start by looking at how
