We start by looking at the well-known types you can bind to.

## *7.6.1 Injecting well-known types*

Throughout this book you've seen examples of several well-known types that you can inject into your endpoint handlers, the most notable one being `HttpContext`. The remaining well-known types provide shortcuts for accessing various properties of the `HttpContext` object.

**NOTE** As described in chapter 3, `HttpContext` acts as a storage box for everything related to a single a request. It contains access to all the low-level details about the request and the response, plus any application services and features you might need.

You can use a well-known type in your endpoint handler by including a parameter of the appropriate type. To access the `HttpContext` in your handler, for example, you could use

```
app.MapGet("/", (HttpContext context) => "Hello world!");
```

You can use the following well-known types in your minimal API endpoint handlers:

- `HttpContext`—This type contains all the details on both the request and the response. You can access everything you need from here, but often, an easier way to access the common properties is to use one of the other well-known types.
- `HttpRequest`—Equivalent to the property `HttpContext.Request`, this type contains all the details about the request only.
