- `HttpResponse`—Equivalent to the property `HttpContext.Response`, this type contains all the details about the response only.
- `CancellationToken`—Equivalent to the property `HttpContext.RequestAborted`, this token is canceled if the client aborts the request. It's useful if you need to cancel a long-running task, as described in my post at http://mng.bz/QP2j.
- `ClaimsPrincipal`—Equivalent to the property `HttpContext.User`, this type contains authentication information about the user. You'll learn more about authentication in chapter 23.
- `Stream`—Equivalent to the property `HttpRequest.Body`, this parameter is a reference to the `Stream` object of the request. This parameter can be useful for scenarios in which you need to process large amounts of data from a request efficiently, without holding it all in memory at the same time.
- `PipeReader`—Equivalent to the property `HttpContext.BodyReader`, `PipeReader` provides a higher-level API compared with `Stream`, but it's useful in similar scenarios. You can read more about PipeReader and the System.IO.Pipelines namespace at http://mng.bz/XNY6.

You can access each of the latter well-known types by navigating via an injected `HttpContext` object if you prefer. But injecting the exact object you need generally makes for code that's easier to read.
